# **Denoising Autoencoders And Where To Find Them**

Today we're going to train deep autoencoders and apply them to faces and similar images search.

Our new test subjects are human faces from the <a href="Ifw dataset (http://vis-www.cs.umass.edu/lfw/">Ifw dataset (http://vis-www.cs.umass.edu/lfw/</a>).

### Import stuff

```
In [3]:
         1 import sys
          2 | sys.path.append("..")
          3 import grading
In [4]:
         1 import tensorflow as tf
          2 import keras, keras.layers as L, keras.backend as K
         3 import numpy as np
         4 from sklearn.model_selection import train_test_split
         5 from lfw_dataset import load_lfw_dataset
         6 %matplotlib inline
         7 import matplotlib.pyplot as plt
         8 import download_utils
         9 import keras_utils
         10 import numpy as np
         11 | from keras_utils import reset_tf_session
```

Using TensorFlow backend.

```
In [5]: 1 # !!! remember to clear session/graph if you rebuild your graph to avoid out-of-memory errors !!!
```

### **Autoencoder architecture**

Let's design autoencoder as two sequential keras models: the encoder and decoder respectively.

We will then use symbolic API to apply and train these models.

# First step: PCA

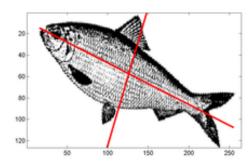

Principial Component Analysis is a popular dimensionality reduction method.

Under the hood, PCA attempts to decompose object-feature matrix X into two smaller matrices: W and  $\hat{W}$  minimizing \_mean squared error\_:

$$||(XW)\hat{W} - X||_2^2 \to_{W,\hat{W}} \min$$

- $X \in \mathbb{R}^{n \times m}$  object matrix (**centered**);
- $W \in \mathbb{R}^{\textit{m} \times \textit{d}}$  matrix of direct transformation;
- $\hat{W} \in \mathbb{R}^{d \times m}$  matrix of reverse transformation;
- ullet n samples, m original dimensions and d target dimensions;

In geometric terms, we want to find d axes along which most of variance occurs. The "natural" axes, if you wish.

PCA can also be seen as a special case of an autoencoder.

- **Encoder**: X -> Dense(d units) -> code
- Decoder: code -> Dense(m units) -> X

Where Dense is a fully-connected layer with linear activaton:  $f(X) = W \cdot X + \vec{b}$ 

Note: the bias term in those layers is responsible for "centering" the matrix i.e. substracting mean.

```
In [10]:
           1 def build_pca_autoencoder(img_shape, code_size):
           2
                  Here we define a simple linear autoencoder as described above.
           3
           4
                  We also flatten and un-flatten data to be compatible with image shapes
           5
           6
           7
                  encoder = keras.models.Sequential()
                  encoder.add(L.InputLayer(img_shape))
           8
           9
                  encoder.add(L.Flatten())
                                                            #flatten image to vector
          10
                  encoder.add(L.Dense(code_size))
                                                            #actual encoder
          11
                  decoder = keras.models.Sequential()
          12
                  decoder.add(L.InputLayer((code_size,)))
          13
                  decoder.add(L.Dense(np.prod(img_shape)))
                                                            #actual decoder, height*width*3 units
          14
          15
                  decoder.add(L.Reshape(img_shape))
                                                            #un-flatten
          16
          17
                  return encoder,decoder
```

Meld them together into one model:

```
In [11]:
           1 %%time
           2 s = reset_tf_session()
           4 encoder, decoder = build_pca_autoencoder(IMG_SHAPE, code_size=32)
           5
           6 inp = L.Input(IMG_SHAPE)
           7 | code = encoder(inp)
           8 reconstruction = decoder(code)
          10 autoencoder = keras.models.Model(inputs=inp, outputs=reconstruction)
             autoencoder.compile(optimizer='adamax', loss='mse')
          11
          12
          13 autoencoder.fit(x=X_train, y=X_train, epochs=15,
          14

Epoch 10/15

# Going deeper: convolutional autoencoder

PCA is neat but surely we can do better. This time we want you to build a deep convolutional autoencoder by... stacking more layers.

#### **Encoder**

The **encoder** part is pretty standard, we stack convolutional and pooling layers and finish with a dense layer to get the representation of desirable size ( code\_size ).

We recommend to use activation='elu' for all convolutional and dense layers.

We recommend to repeat (conv, pool) 4 times with kernel size (3, 3), padding='same' and the following numbers of output channels: 32, 64, 128, 256.

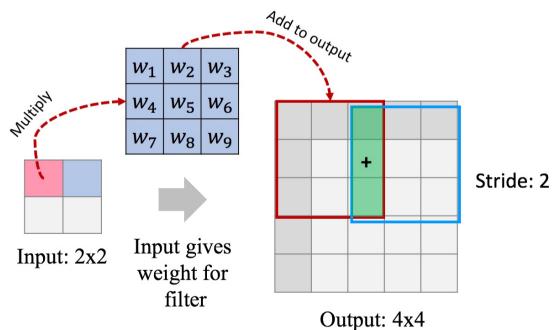

Remember to flatten ( L.Flatten() ) output before adding the last dense layer!

#### **Decoder**

For decoder we will use so-called "transpose convolution".

Traditional convolutional layer takes a patch of an image and produces a number (patch -> number). In "transpose convolution" we want to take a number and produce a patch of an image (number -> patch). We need this layer to "undo" convolutions in encoder. We had a glimpse of it during week 3 (watch <a href="this video">this video</a> (<a href="https://www.coursera.org/learn/intro-to-deep-learning/lecture/auRqf/a-glimpse-of-other-computer-vision-tasks">this video</a> (<a href="https://www.coursera.org/learning/lecture/auRqf/a-glimpse-of-other-computer-visi

Here's how "transpose convolution" works:

In this example we use a stride of 2 to produce 4x4 output, this way we "undo" pooling as well. Another way to think about it: we "undo" convolution with stride 2 (which is similar to conv + pool).

You can add "transpose convolution" layer in Keras like this:

```
L.Conv2DTranspose(filters=?, kernel_size=(3, 3), strides=2, activation='elu', padding='same')
```

Our decoder starts with a dense layer to "undo" the last layer of encoder. Remember to reshape its output to "undo" L.Flatten() in encoder.

Now we're ready to undo (conv, pool) pairs. For this we need to stack 4 L.Conv2DTranspose layers with the following numbers of output channels: 128, 64, 32, 3. Each of these layers will learn to "undo" (conv, pool) pair in encoder. For the last L.Conv2DTranspose layer use activation=None because that is our final image.

```
In [14]:
          1 # Let's play around with transpose convolution on examples first
          2 def test_conv2d_transpose(img_size, filter_size):
                 print("Transpose convolution test for img_size={}, filter_size={}:".format(img_size, filter_size))
          3
          4
          5
                 x = (np.arange(img_size ** 2, dtype=np.float32) + 1).reshape((1, img_size, img_size, 1))
                 f = (np.ones(filter_size ** 2, dtype=np.float32)).reshape((filter_size, filter_size, 1, 1))
          6
          7
          8
                 s = reset_tf_session()
          9
          10
                 conv = tf.nn.conv2d_transpose(x, f,
                                               output_shape=(1, img_size * 2, img_size * 2, 1),
          11
          12
                                               strides=[1, 2, 2, 1],
          13
                                               padding='SAME')

# **Optional: Denoising Autoencoder**

This part is **optional**, it shows you one useful application of autoencoders: denoising. You can run this code and make sure denoising works:)

Let's now turn our model into a denoising autoencoder:

We'll keep the model architecture, but change the way it is trained. In particular, we'll corrupt its input data randomly with noise before each epoch.

There are many strategies to introduce noise: adding gaussian white noise, occluding with random black rectangles, etc. We will add gaussian white noise.

```
In [25]:
           1 def apply_gaussian_noise(X,sigma=0.1):
           2
                  adds noise from standard normal distribution with standard deviation sigma
           3
           4
                  :param X: image tensor of shape [batch,height,width,3]
           5
                  Returns X + noise.
           6
           7
                  ### YOUR CODE HERE ###
           8
                  size, row, col, ch = X.shape
           9
                 mean = 0
          10
                 gauss = np.random.normal(mean, sigma, (size, row, col, ch))
          11
                 noise = gauss.reshape(size, row, col, ch)
          12
                  return X + noise
In [26]:

# Optional: Image retrieval with autoencoders

So we've just trained a network that converts image into itself imperfectly. This task is not that useful in and of itself, but it has a number of awesome side-effects. Let's see them in action.

First thing we can do is image retrieval aka image search. We will give it an image and find similar images in latent space:

Let's compare the codes!

To speed up retrieval process, one should use Locality Sensitive Hashing on top of encoded vectors. This <u>technique</u> (<a href="https://erikbern.com/2015/07/04/benchmark-of-approximate-nearest-neighbor-libraries.html">https://erikbern.com/2015/07/04/benchmark-of-approximate-nearest-neighbor-libraries.html</a>) can narrow down the potential nearest neighbours of our image in latent space (encoder code). We will caclulate nearest neighbours in brute force way for simplicity.

```
In [30]:

```

That's it!

Of course there's a lot more you can do with autoencoders.

If you want to generate images from scratch, however, we recommend you our honor track on Generative Adversarial Networks or GANs.
